Abstract

A plate (16) or oblong rail covers the bone surface where this has been cut, and forms a radial collar protruding from the stem (2). The maximum overall width of the plate or rail is at least one and a half times the external dia. of the stem at the distal end, and it has no sharp edges at its radial edge. The prosthesis (1) can have a single stem inserted in the passage of the femur, and the plate can form a round mushroom head (3) with curved surface in the distal direction, while the stem is at the center of the proximal surface of the head.
